A MATHEMATICAL THEORY
FOR
VISCOUS, FREE-SURFACE FLOWS
OVER A PERTURBED PLANE*

F. ABERGEL† AND J.L. BONA‡

Abstract. Considered here are steady, two-dimensional motions of an incompressible, Newtonian fluid flowing under gravity down an inclined channel. In case the bottom of the channel is flat, the flow is the classical Poiseuille-Nusselt flow and the free surface is then a plane parallel to the bottom. Motivated by the recent experimental and numerical studies of Pritchard, Scott and Tavener, we look at bottom configurations which possess some localized, non-uniform structure. An existence theory for steady, highly viscous flow is presented relating to this context. An important consequence of our theory is that the steady flows whose existence is established decay exponentially rapidly to the unperturbed Poiseuille-Nusselt flow away from the local variation in the channel bottom profile.

1. Introduction. The determination of the free surface in fluid flows all of whose boundaries are not constrained is a problem of both scientific and practical interest. Many industrial processes and natural phenomena feature fluid motion with steady or evolutionary free surfaces and this has given a lot of impetus to the study of such flows.

Several years ago, Pritchard (1986) concluded a study of the flow of viscous fluid off the end of a finite, inclined channel. In his experiments, which turned up some very interesting phenomena, the flows were dominated by viscosity and surface tension effects. While the range of both steady and time-dependent flows discovered was fascinating, they appear to be beyond the reach of our present analytical or numerical tools. This prompted another related experiment which held out more hope for both rigorous analytical treatment and computational analysis. In this experiment, fluid flows at a constant rate under gravity down an inclined channel whose bottom is planar except for a pair of smooth bumps (see Figure 1). The fluid pours off the end of the channel into a reservoir and is then pumped back to the top of the channel. For relatively small flow rates, these motions are also dominated by viscous and surface-tension effects. Pritchard observes interesting steady flows in this situation and these flows are used to check the accuracy of a numerical scheme. This work is reported in a forthcoming paper by Pritchard, Scott and Tavener (1990).

Figure 1.

Our purpose here is to provide an analytical framework modelling these flows and a rigorous existence theory for steady motion corresponding to a wide range of bottom configurations including the one described above. The long, but finite channel used in the experiments is here modelled by an infinitely long channel. An interesting and useful by-product of our theory is that the steady flows corresponding to a bottom perturbation of finite extent decay exponentially rapidly to Poiseuille-Nusselt flow as one moves away from the perturbation. This result is helpful in formulating and analyzing the aforementioned numerical scheme. The analytical model assumes an infinitely long channel as a way of getting around the specification of potentially complicated boundary conditions inherent in the consideration of a finite channel. The numerical scheme must be constructed relative to a finite domain, however, and so the issue of boundary conditions cannot be ignored. However, because of the rapid decay to Poiseuille-Nusselt flow, it is reasonable to impose exactly the Poiseuille-Nusselt flow conditions at both the upstream and downstream boundaries, provided these are situated a reasonable distance from the part of the channel bottom that has non-uniform (but two-dimensional) structure.
Precursors of the present work include the work of Jean (1980), Solonnikov (1980, 1982, 1983) which was concerned with a finite channel. After the present work was completed, we also became aware of another, more recent paper of Solonnikov's (1989) which deals with a related, though somewhat different problem in which liquid pours down an inclined plane into an infinite reservoir. In this latter problem, the flow approaches a Poiseuille-Nusselt flow upstream and is matched to a Jeffrey-Hamel flow in a sector of the reservoir.

The plan of the paper is as follows. Section 2 lays out the model and the governing equations while Section 3 contains a reformulation of the mathematical issue as a fixed-point problem for a mapping $T$. A central, technical result, Theorem 3.1, concerning the mapping $T$ is stated at this point. The proof of this result occupies the next three sections. Taking it that both the bottom configuration and the free surface are known, the flow domain is mapped to a fixed domain and the velocity field is determined via the stream function in Section 4. In Section 5, the associated pressure field is determined, leading to a short proof of Theorem 3.1 in Section 6. The existence and uniqueness theorem for the free-surface flow is then shown in Section 7 to follow from an implicit-function theorem argument. Sections 8 and 9 are devoted to establishing the validity of the hypotheses that are needed to invoke the implicit-function theorem. The last section contains the proof of a technical result that arose in Section 4, whilst the Appendix records the calculation of the functional derivatives of the mapping that sends a known flow domain onto a fixed, infinite strip.

2. The Governing Equations. Attention will be given to the situation depicted in Figure 1, namely the flow of a viscous liquid down an infinitely long channel of uniform width, the bed of which is located at a height $g(x)$ above a plane $P$ that slopes at an angle $\alpha$. It is supposed that the coordinate frame $(x, y)$ is located in this plane and that $g$ is measured in the direction $y$ normal to the plane. In this set of coordinates, we shall further suppose the bottom configuration $g$ of the channel to be smooth and have compact support, so representing a perturbation of finite extent of a perfect, planar surface. In fact, it will only be required that $g$ rapidly approach zero both upstream and downstream. It is assumed that the fluid motion is steady and two-dimensional. The resulting free surface is taken to be the curve $y = y_0 + \gamma(x)$ and $\gamma$ represents the principal unknown in the problem while $y_0$ is the height of the free surface above $P$ in the limit as $|x|$ becomes unboundedly large. It is expected that the steady flow will tend to the classical Poiseuille-Nusselt flow corresponding to the liquid depth $y_0$ far upstream and downstream of the portion of the bottom that is not essentially flat. If we let

$$\Omega_g^2 = \{(x, y): -\infty < x < \infty, \quad g(x) < y < y_0 + \gamma(x)\}$$

denote the flow domain, then this latter expectation leads to the following mathematical formulation of our problem.

Given a bottom configuration $g$, find a function $\gamma : \mathbb{R} \to \mathbb{R}$ (the free surface), a vector-valued function $u$ (the velocity field) and a scalar function $p$ (the pressure field) defined
on $\Omega^*_y$ such that

\begin{equation}
\begin{aligned}
- \Delta u + \nabla p &= \left( \frac{C_1}{C_2} \right) \text{ in } \Omega^*_y, \\
\nabla \cdot u &= 0 \quad \text{in } \Omega^*_y, \\
u(x, g(x)) &= 0, \quad (u \cdot n)(x, y_0 + \gamma(x)) = 0, \\
(\nabla_S u \cdot n \cdot t)(x, y_0 + \gamma(x)) &= 0;
\end{aligned}
\end{equation}

\begin{equation}
\frac{\gamma''(x)}{(1 + (\gamma'(x))^2)^{3/2}} = \tau \left\{ -p(x, y_0 + \gamma(x)) + (\nabla_S u \cdot n)(x, y_0 + \gamma(x)) \right\};
\end{equation}

\begin{equation}
\lim_{|x| \to \infty} u(x, y) = u_P(y) = \begin{bmatrix} C_1 (y_0 y - \frac{1}{2} y^2) \\ 0 \end{bmatrix}, \quad \lim_{|x| \to \infty} p(x, y) = p_P(y) = C_2 (y - y_0).
\end{equation}

In this formulation, we have taken the kinematic viscosity and the density to both have the value one. Additionally, the flows are taken to be sufficiently slow that inertial effects can be ignored, so the nonlinear term as well as the time derivative in the Navier-Stokes equations has been set to zero. For the equations above, $C_1 = \rho \sin(\alpha) > 0, C_2 = -\rho \cos(\alpha) < 0$ are the components of the gravitational force field in the chosen coordinate frame, $(t, n)$ is the positively oriented Frénet frame on the boundary with $n$ pointing outward, and $g$ is the gravity constant. Furthermore, $\nabla_S u := \frac{1}{2} (\nabla u + \nabla u^T)$ is the deviatoric part of the stress tensor $\sigma := -pI + \nabla_S u$; the boundary conditions in (2.1) are a non-slip condition at the solid boundary, a contact condition at the free surface, and a zero-shear-stress condition at the free surface. Equation (2.2) is the condition of equilibrium for the free surface, and the positive constant $\tau$ is the surface-tension coefficient, while (2.3) assigns a prescribed behaviour of the velocity- and pressure-fields at infinity, that of the standard Poiseuille-Nusselt flow with height $y_0$. The latter, whose velocity and pressure field are represented by $u_P, p_P$, respectively, corresponds to $g = \gamma \equiv 0$.

3. **Formulation as a Fixed-Point Problem.** The functional-analytic setting to be used in the analysis of (2.1), (2.2), (2.3) is introduced and the problem of finding a suitable solution of the equations is recast as the problem of finding a fixed point of a certain operator.

First, the function spaces that are central to our analysis are defined. Given $c > 0$, $m \geq 0$ an integer and $\lambda$ with $0 < \lambda < 1$, we define $B^{m,\lambda}_c(\mathbb{R})$ to be the linear space

\begin{equation}
\{ f \in C^{m,\lambda}(\mathbb{R}) : \sum_{0 \leq k \leq m} \sup_{x \in \mathbb{R}} e^{c|x|} |D_x^k f(x)| < \infty \},
\end{equation}

where $C^{m,\lambda}(\mathbb{R})$ is the usual Hölder class. The space $B^{m,\lambda}_c(\mathbb{R})$ is a Banach algebra with the norm

\begin{equation}
\| f \|_{m, c, \lambda} := \sum_{k=0}^{m} \sup_{x \in \mathbb{R}} e^{c|x|} |D_x^k f(x)| + \sup_{(x, x') \in \mathbb{R}^2, x \neq x'} \frac{|D_x^m f(x) - D_x^m f(x')|}{|x - x'|^\lambda},
\end{equation}

4
or with the equivalent norm

$$(3.3) \quad |f|_{m,c,\lambda} = \sup_{x \in \mathbb{R}} \left[ e^{c|x|} (|f(x)| + |D_x^m f(x)|) \right] + \sup_{x \neq x'} \frac{|D_x^m f(x) - D_x^m f(x')|}{|x - x'|^\lambda}. $$

Remark 3.1. In addition to defining a Banach-algebra structure on $B_c^{m,\lambda}(\mathbb{R})$, the bilinear mapping $(f,g) \mapsto fg$ is continuous as a mapping of $B_c^{m,\lambda}(\mathbb{R}) \times C^{\lambda}(\mathbb{R})$ into $B_c^{m',\lambda}(\mathbb{R})$ where $m' = \min\{m,n\}$. This easy result will find use later.

The operator $T$ central to the subsequent analysis is now introduced. Suppose that $(g,\gamma)$ lie in $B_c^{1,\lambda}(\mathbb{R}) \times B_c^{1,\lambda}(\mathbb{R})$ and suppose they are restricted in size in a way to be made precise in the next section. Then the domain $\Omega_g$ is well defined and one can solve in principle equations (2.1) with the asymptotic conditions (2.3) for the velocity field $u$ and the pressure $p$. Taking these as determined, it is then possible to solve the differential equation

$$\mathcal{L}T := D_x^2 T - \tau C_1 y_0 D_x^2 T + \tau C_2 D_x T + 3\tau \frac{C_1}{y_0} T =$$

$$(3.4) \quad \tau D_x \left\{ (1 + (\gamma'(x))^2)^{3/2} [-p(x,y_0 + \gamma(x)) + (\nabla u \cdot n \cdot n)(x,y_0 + \gamma(x))] \right\}$$

$$- \tau C_1 y_0 D_x^2 \gamma + \tau C_2 D_x \gamma + 3\tau \frac{C_1}{y_0} \gamma$$

for $x \in \mathbb{R}$. The solution $T = T(g,\gamma)$ of (3.4) is not in general a solution of the original surface tension equation (2.2). Indeed, equation (2.2) has been considerably modified for technical reasons. However, it transpires that if $T(g,\gamma) = \gamma$, then (3.4) and (2.2) are indeed equivalent.

The idea behind our theory is to apply the implicit-function theorem to the operator $\gamma - T(g,\gamma)$. This approach seems natural since $T(0,0) = 0$, a relation that corresponds to the fact that if the bottom of the channel is perfectly planar, then the Poiseuille-Nusselt flow $(u,p) = (u_p,p_p)$ with a planar free surface at height $y_0$ above the channel bed is a solution of the flow problem (2.1)-(2.3). The seemingly awkward choice for $T$ in (3.4) will appear as quite natural in the calculations to appear subsequently.

Here is the principal qualitative result concerning the operator $T$. The proof of the result is somewhat lengthy, and comprises most of the content of Sections 4, 5 and 6.

**Theorem 3.1.** Let a value $\tau$ of the surface-tension parameter and a Hölder exponent $\lambda \in (0,1)$ be given, and let $y_0 > 0$ be specified. Then there exists a value $\epsilon_1 > 0$ and $\rho_0 > 0$ such that if $0 < \epsilon = \sin(\alpha) < \epsilon_1$ and $0 < c < \min\{\tilde{c},r_2(\epsilon)\}$, where $\tilde{c}$ and $r_2(\epsilon)$ are defined in Proposition 4.2 and Lemma 4.1, respectively, then (i) $T$ is well defined from the open ball $B_0$ of radius $\rho_0$ centered at the origin in $B_c^{1,\lambda} \times B_c^{1,\lambda}$ into $B_c^{1,\lambda}$, and (ii) $T$ is continuously Fréchet differentiable on $B_0$. 5
As mentioned before, this qualitative theorem will require some effort. In the next section, for sufficiently small $g$ and $\gamma$, we will map $\Omega_g^\gamma$ onto a fixed, infinite strip. The velocity field may then be determined as a function of $(g, \gamma)$. In Section 5, a similar determination of the pressure is made. In Section 6, the differential equation (3.4) is analyzed and this puts the finishing touches on the proof of Theorem 3.1.

4. The Dependence of the Velocity on $(g, \gamma)$. Because the velocity field is divergence free, we can write $u$ as $\nabla \times \Psi$. Taking account of the asymptotic conditions (2.3) we expect the flow to satisfy, it seems prudent to write $\Psi = \Phi + \psi$ where $\Phi$ is a stream function in $\Omega_g^\gamma$ closely associated to Poiseuille-Nusselt flow, chosen to satisfy as many boundary conditions as possible. One then envisions working with the perturbation stream function $\psi$ as a primary dependent variable, and expects that it will decay to zero at infinity. An appropriate choice for $\Phi$ which will be used throughout is

\begin{equation}
\Phi(x, y) = C_1 \left\{ \frac{y_0}{2} \left( \frac{y_0(y - g(x))}{y_0 + \gamma(x) - g(x)} \right)^2 - \frac{1}{6} \left( \frac{y_0(y - g(x))}{y_0 + \gamma(x) - g(x)} \right)^3 \right\}.
\end{equation}

Naturally, the bottom profile $g$ and the putative free surface $\gamma$ are not unrestricted in size here. However, if

\begin{equation}
\max \left\{ \sup_{x \in \mathbb{R}} |g(x)|, \sup_{x \in \mathbb{R}} |\gamma(x)| \right\} < \frac{y_0}{2},
\end{equation}

then $\Omega_g^\gamma$ is indeed a well-defined, connected domain and $\Phi$ is a smooth function of $g$ and $\gamma$ in this domain. The assumption (4.2) will be in force throughout our analysis. If one takes the curl of the equation in (2.1) and rewrites everything in terms of $\psi$, one obtains the following boundary-value problem for $\psi$:

\begin{equation}
\begin{aligned}
\Delta^2 \psi &= -\Delta^2 \Phi & \text{in} \ \Omega_g^\gamma, \\
\psi(x, g(x)) &= \frac{\partial \psi}{\partial y}(x, g(x)) = 0 \quad \text{for} \ x \in \mathbb{R}, \\
\psi(x, y_0 + \gamma(x)) &= 0 \quad \text{for} \ x \in \mathbb{R}, \\
\frac{1}{2}(1 - \gamma'(x)) \left( \frac{\partial^2 \psi}{\partial y^2} - \frac{\partial^2 \psi}{\partial x^2} \right)(x, y_0 + \gamma(x)) &- 2\gamma'(x) \frac{\partial^2 \psi}{\partial x \partial y}(x, y_0 + \gamma(x)) = \\
- \frac{1}{2}(1 - \gamma'(x)) \left( \frac{\partial^2 \Phi}{\partial y^2} - \frac{\partial^2 \Phi}{\partial x^2} \right)(x, y_0 + \gamma(x)) &+ 2\gamma'(x) \frac{\partial^2 \Phi}{\partial x \partial y}(x, y_0 + \gamma(x))
\end{aligned}
\end{equation}

for $x \in \mathbb{R}$

where $\Delta^2 = \frac{\partial^2}{\partial x^2} + 2\frac{\partial^2}{\partial x \partial y} + \frac{\partial^2}{\partial y^2}$ is the bi-Laplacian and the boundary conditions follow from those imposed on $u$ except that in principle one only has $\psi(x, g(x)) = \psi(x, y_0 + \gamma(x)) = \text{constant}$, but we have chosen this constant to be zero.
Consider the change of variables

\[(4.4) \quad \hat{x} = x, \quad \hat{y} = \frac{y_0(y - g(x))}{y_0 + \gamma(x) - g(x)},\]

which maps $\Omega^2_\gamma$ onto the strip $\Sigma = \mathbb{R} \times (0, y_0)$. Let $\hat{\psi}$ be defined in $\Sigma$ by $\hat{\psi}(\hat{x}, \hat{y}) = \psi(x, y)$ and introduce the space

\[B^m_c(\Sigma) := \left\{ \hat{\psi} \in C^m(\Sigma) : \sup_{k + \ell \leq m} \sup_{(\hat{x}, \hat{y}) \in \Sigma} e^{\|\hat{x}\|} |D^k_x D^\ell_y \hat{\psi}(\hat{x}, \hat{y})| < +\infty \right\}\]

modelled after $B^m(\mathbb{R})$. The norm of a function $\hat{\psi}$ in $B^m_c(\Sigma)$ is defined to be

\[(4.5) \quad \|\hat{\psi}\|_{m, c, \lambda} = \sum_{k + \ell \leq m} \sup_{(\hat{x}, \hat{y}) \in \Sigma} e^{\|\hat{x}\|} |D^k_x D^\ell_y \hat{\psi}(\hat{x}, \hat{y})| + \sup_{\lambda > 0} \frac{|D^k_x D^\ell_y \hat{\psi}(\hat{x}, \hat{y}) - D^k_x D^\ell_y \hat{\psi}(\hat{x}', \hat{y}')|}{((\hat{x} - \hat{x}')^2 + (\hat{y} - \hat{y}')^2)^{\lambda/2}}.\]

The space $B^m_c(\Sigma)$ equipped with this norm is a Banach algebra. One can also define $|\hat{\psi}|_{m, c, \lambda}$ the analogue of (3.3); furthermore, Remark 2.1 is easily extended to the case of functions in $\Sigma$.

With these preliminaries in hand, the main result of this section is now stated.

**Theorem 4.1.** There exists an open ball $\mathcal{B}$ of radius $r_0 > 0$, centered at the origin in $B^4_c(\mathbb{R}) \times B^4_c(\mathbb{R})$ such that whenever $(g, \gamma) \in \mathcal{B}$, the following statements hold:

(i) Problem (4.3) has a unique solution $\psi$,

(ii) $\hat{\psi}$, the image of $\psi$ through the change of variables (4.4), is in $B^4_c(\Sigma)$, and

(iii) the mapping $S : (g, \gamma) \rightarrow \hat{\psi}$ is continuously differentiable from $\mathcal{B}$ into $B^4_c(\Sigma)$.

The following proposition will aid materially in the proof of Theorem 4.1. Its somewhat technical proof is postponed until Section 10.

**Proposition 4.2.** Consider the boundary value problem

\[(4.6) \quad \begin{align*}
\Delta^2 v &= b_1 \text{ in } \Sigma; \quad v(\hat{x}, 0) = b_2(\hat{x}) \quad \hat{x} \in \mathbb{R}; \\
\frac{\partial \hat{v}}{\partial \hat{y}}(\hat{x}, 0) &= b_3(\hat{x}) \quad \hat{x} \in \mathbb{R}; \quad \hat{v}(\hat{x}, y_0) = b_4(\hat{x}) \quad \hat{x} \in \mathbb{R}; \\
\frac{1}{2} \left( \frac{\partial^2 v}{\partial \hat{y}^2} - \frac{\partial^2 v}{\partial \hat{x}^2} \right)(\hat{x}, y_0) &= b_5(\hat{x}) \quad \hat{x} \in \mathbb{R};
\end{align*}\]

with the assumptions that $(b_1, b_2, b_3, b_4, b_5) \in B^6_c(\Sigma) \times B^4_c(\mathbb{R}) \times B^3_c(\mathbb{R}) \times B^4_c(\mathbb{R}) \times B^2_c(\mathbb{R})$. There exists $\hat{c} > 0$ depending only on $y_0$ such that whenever $0 < c < \hat{c}$, Problem (4.6) has a
unique solution \( v \in B^4_c(\bar{\Sigma}) \). Furthermore, the solution map is a topological isomorphism between the corresponding spaces. Finally, the norm of the solution map is bounded on any compact subinterval of \([0, \bar{c}]\).

Proof (of Theorem 4.1). The boundary-value problem (4.3) for \( \psi \) transforms under the change of variables (4.4) into a boundary value problem for \( \hat{\psi} \) on \( \Sigma \). Consider for instance the differential operators \( \frac{\partial}{\partial x} \), and \( \frac{\partial}{\partial y} \), they transform, respectively, into

\[
\frac{\partial}{\partial x} + \frac{(-g' y_0^2 - g' y_0 y' - y_0 y' + y_0 y' + y_0 g' \gamma)}{(y_0 + \gamma - g)^2} \frac{\partial}{\partial y} \quad \text{and} \quad \frac{y_0}{y_0 + \gamma - g} \frac{\partial}{\partial y},
\]

thanks to the particular change of variables. Iterating this result, one sees that the differential operator \( \frac{\partial^k}{\partial x^k \partial y^{k-p}} \) transforms into

\[
(4.7) \quad \frac{\partial^k}{\partial x^k \partial y^{k-p}} + \frac{1}{(y_0 + \gamma - g)^{n(k)}} \sum_{q_1 + q_2 \leq k} P_{q_1, q_2} \frac{\partial^{q_1 + q_2}}{\partial x^{q_1} \partial y^{q_2}},
\]

where \( P_{q_1, q_2} \) is a polynomial in the \((2k + 2)\) functions \( (g, g', \ldots, D^k_x g, \gamma, \gamma', \ldots, D^k_x \gamma) \) such that \( P_{q_1, q_2}(0) = 0 \). As for \( n(k) \), it is an integer depending on \( k \). It follows that the boundary-value problem for \( \hat{\psi} \) is a perturbation of Problem (4.6) on \( \Sigma \). More precisely, denote by \( \mathcal{A} \) the linear operator defined by

\[
(4.8) \quad \mathcal{A} : B^4_c(\bar{\Sigma}) \to B^0_c(\bar{\Sigma}) \times B^4_c(\bar{\Sigma}) \times B^4_c(\bar{\Sigma}) \times B^3_c(\bar{\Sigma}) \times B^2_c(\bar{\Sigma})
\]

\[
\begin{align*}
&v \mapsto \left( \Delta^2 v, v(\cdot, 0), v(\cdot, 0), \frac{\partial v}{\partial y}(\cdot, 0), \frac{1}{2} \left( \frac{\partial^2 v}{\partial y^2} - \frac{\partial^2 v}{\partial x^2} \right)(\cdot, y_0) \right),
\end{align*}
\]

and let \( \mathcal{A}_{g}^\gamma \) be the corresponding operator, for \( g, \gamma \) non zero, resulting from the change of variables (4.4). Denoting by \( Y \) the target space of \( \mathcal{A} \) and using the expressions in (4.7), we easily verify that

\[
(4.9) \quad \| (\mathcal{A} - \mathcal{A}_{g}^\gamma) v \|_Y \leq L \left( \| g \|_{4, c, \lambda}, \| \gamma \|_{4, c, \lambda} \right) \| v \|_{4, c, \lambda},
\]

where \( L \) is a continuous function with \( L(0, 0) = 0 \). In fact, because of Remark 2.1, one can replace the norms of \( g \) and \( \gamma \) in \( B^4_c(\bar{\Sigma}) \) by their norms in the (unweighted) Hölder space \( C^4(\bar{\Sigma}) \), and (4.9) remains valid; indeed, \( L \) is independent of the value of \( c \). Now, we use the fact established in Proposition 4.2 that \( \mathcal{A} \) is a continuous isomorphism to assert the existence of an \( r_0 \) such that \( \mathcal{A}_{g}^\gamma \) is also an isomorphism provided that

\[
(4.10) \quad \| g \|_{4, c, \lambda} + \| \gamma \|_{4, c, \lambda} \leq r_0.
\]

In order to prove (ii) (and, by the same token, (i)), one just needs to verify that the right-hand sides for the boundary-value problem for \( \psi \) belong to \( Y \), a fact that is established by straightforward calculations.
Attention is now given to the differentiability of $S$. Define two mappings $S_1$ and $S_2$ as follows:

$$S_1 : \mathcal{B} \rightarrow \mathcal{L}(B_c^{4,\lambda}(\tilde{\Sigma}), y)$$

$$(g, \gamma) \mapsto A_{\gamma}^g$$

and

$$S_2 : \text{Isom}(B_c^{4,\lambda}(\tilde{\Sigma}), y) \rightarrow \text{Isom}(y, B_c^{4,\lambda}(\tilde{\Sigma}))$$

$$L \mapsto L^{-1}.$$ 

Then it follows that

$$S(g, \gamma) = (S_2 \circ S_1(g, \gamma))(\mathcal{F}(g, \gamma)),$$

where $\mathcal{F}(g, \gamma)$ is the right-hand side of the boundary value problem for $\hat{\psi}$; in fact, $\mathcal{F}(g, \gamma) = -A_{\gamma}^g(\hat{\Phi}) + (0, 0, C_1 \frac{1}{3} y_0^3, 0, 0)$ where $\hat{\Phi}$ is the image of $\Phi$ defined in (4.1) under the change of variables (4.4), i.e. $\hat{\Phi}(\hat{x}, \hat{y}) = C_1 \left( \frac{1}{2} y_0 \hat{y}^2 - \frac{1}{6} \hat{y}^3 \right)$. As it is well known that $S_2$ is a continuously differentiable mapping, it is simply a matter of combining the chain rule, the product rule and Lemma 4.3 below together with the fact that $\hat{\Phi}$ is independent of $(g, \gamma)$ to conclude the validity of Theorem 4.1. \[\square\]

**Lemma 4.3.** Let $P$ be a rational function of $k$ variables which is devoid of poles in a neighbourhood of the origin in $\mathbb{R}^k$ ($k$ a positive integer) such that $P(0) = 0$. Then the mapping

$$\mathcal{P} : (g_1, \ldots, g_k) \mapsto P(g_1, \ldots, g_k)$$

maps $\Pi_{i=1}^k B_c^{n_i,\lambda}(\mathbb{R})$ into $B_c^{n_0,\lambda}(\mathbb{R})$, where $n_i \geq 0$ are integers, and $n_0 = \min\{n_i : 1 \leq i \leq k\}$; moreover, $\mathcal{P}$ is continuously differentiable in a neighbourhood $\mathcal{N}$ of the origin in $\Pi_{i=1}^k B_c^{n_i,\lambda}(\mathbb{R})$.

**Proof.** It will be shown that $\mathcal{P}$ has continuous first-order partial derivatives with respect to $g_i, 1 \leq i \leq k$. In fact, we show the following:

$$(4.11) \quad \|P(g_1, \ldots, g_i + h, \ldots, g_k) - P(g_1, \ldots, g_k) - \frac{\partial P}{\partial x_i}(g_1, \ldots, g_k)h\|_{n_0, c, \lambda} \leq \|h\|_{n_i, c, \lambda} + o(\|h\|_{n_i, c, \lambda})$$

for $(g_1, \ldots, g_k), (g_1, \ldots, g_i + h, \ldots, g_k) \in \mathcal{N}$, and

$$(4.12) \quad \left\{ \begin{array}{l} \text{the mapping } (g_1, \ldots, g_k) \mapsto \frac{\partial P}{\partial x_i}(g_1, \ldots, g_k) \text{ is continuous from } \\
\mathcal{N} \text{ into } \mathcal{L}(B_c^{n_i,\lambda}(\mathbb{R}), B_c^{n_0,\lambda}(\mathbb{R})) \\
\end{array} \right.$$ 

for $1 \leq i \leq k$. 

9
In the case where $P$ is a polynomial, say

$$P(x_1, \ldots, x_k) = \sum_{0 < q_1 + \cdots + q_k \leq N} a_{q_1 \ldots q_k} x_1^{q_1} \ldots x_k^{q_k},$$

of degree $N$, the binomial expansion may be used to show that

$$P(g_1, \ldots, g_i + h, \ldots, g_k) - P(g_1, \ldots, g_k) - h \left( \sum_{q_1 + \cdots + q_k \leq N, \; q_i \geq 1} q_i a_{q_1 \ldots q_k} g_1^{q_1} \cdots g_i^{q_i-1} \cdots g_k^{q_k} \right)$$

$$= h^2 Q(g_1, \ldots, g_k, h),$$

where $Q$ is a polynomial in $(k + 1)$ variables. Using the fact that $B^\alpha_{c, \lambda} (\mathbb{R})$ is an algebra, (4.11) follows immediately; as for (4.12), it is obviously true since $\frac{\partial P}{\partial x_i}$ is itself a polynomial (see also Remark 2.1).

If, instead, we have

$$P(x_1, \ldots, x_k) = \frac{P_1(x_1, \ldots, x_k)}{a_0 + P_2(x_1, \ldots, x_k)},$$

where $P_1, P_2$ are two polynomials with $P_1(0, \ldots, 0) = P_2(0, \ldots, 0) = 0$ and $a_0 \neq 0$, we proceed as in the classical proof of the quotient rule, and the result follows. \[ \square \]

**Remark 4.1.** When applying Lemma 4.3 in the proof of Theorem 4.1, we consider expressions of the form $P(g, \ldots, D_x^k g, \gamma, \ldots, D_x^k \gamma) \frac{\partial P}{\partial x^2 \partial g^p - q}$; the differentiability of such expressions follows from Lemma 4.3, Remark 2.1, the product rule and the linearity of the mapping $(g, \gamma) \mapsto (g, \ldots, D_x^k g, \gamma, \ldots, D_x^k \gamma)$.

**Remark 4.2.** In what follows, use will be made of the actual expression of the derivative of $S$ with respect to $\gamma$ in a neighbourhood of the origin. However, the formula for this derivative is not needed for arbitrary $g, \gamma$.

**Remark 4.3.** Lemma 4.3 is easily extended to the case of a real analytic function.

**Remark 4.4.** The real number $r_0$ introduced in (4.10) is bounded away from zero provided $c$ runs over a compact subinterval of $[0, \bar{c})$, as is determined by reference to Proposition 4.2.
5. The Dependence of the Pressure on \((g, \gamma)\). For a given bottom profile \(g\) and a free surface \(\gamma\), the pressure field \(p\) in (2.1) is obtained as a standard by-product of the results in Section 4. Classical regularity results [S1] show that \(p\) lies in \(C^{2,\lambda}\) and that \(\nabla p\) is in \(C^{1,\lambda}(\overline{\Omega}_g)\). For the problem under consideration here, what is particularly interesting is the values of \(p\) along the curve \(y = y_0 + \gamma(x)\). Recalling that \(u(x, y) = \nabla \times (\Phi + \psi)(x, y)\) and denoting \(p(x, y_0 + \gamma(x))\) by \(q(x)\), one obtains that

\[
q'(x) = \left( \frac{\partial p}{\partial x} + \gamma'(x) \frac{\partial p}{\partial y} \right) (x, y_0 + \gamma(x))
\]

in the original variables \((x, y)\). Using the first equation in (2.1), \(q'(x)\) can be expressed in a more complicated way as

\[
q'(x) = C_1 + C_2 \gamma'(x) + \Delta \left( \frac{\partial}{\partial y} (\Phi + \psi) \right) - \gamma'(x) \Delta \left( \frac{\partial}{\partial x} (\Phi + \psi) \right)
\]

where the functions of two variables in this last formula are all evaluated at \((x, y_0 + \gamma(x))\).

It is straightforward to check that \(\Delta \left( \frac{\partial \Phi}{\partial y} \right) (x, y_0 + \gamma(x)) + C_1\) belongs to \(B^{1,\lambda}(\mathbb{R})\), and therefore it transpires that \(q'\) belongs to \(B^{1,\lambda}_c(\mathbb{R})\). The function \(q\) is determined from \(q'\) by setting it equal to zero at \(-\infty\) so that

\[
q(x) = C_2 \gamma(x) + \int_{-\infty}^{x} \left[ \Delta \left( \frac{\partial}{\partial y} (\psi + \Phi) \right) - \gamma'(s) \Delta \left( \frac{\partial}{\partial x} (\psi + \Phi) \right) (s, y_0 + \gamma(s)) + C_1 \right] ds.
\]

This step is legitimate thanks to the exponential decay of the integrand at \(-\infty\). It is not necessarily true that \(q\) itself decays exponentially at \(+\infty\), and this is the principal reason why Equation (2.2) has been so severely modified in the definition of \(T\) given in (3.4).

The main result of this section is the following proposition.

**Proposition 5.1.** Let \((g, \gamma)\) be in the open ball \(\mathcal{B}\) whose existence was established in Theorem 4.1 and let \(R\) be the mapping \((g, \gamma) \mapsto q\), where \(q\) is defined in (5.2). Then it follows that

(i) \(R\) is continuously differentiable from \(\mathcal{B}\) into \(C^{2,\lambda}(\mathbb{R})\), and that

(ii) the mapping \((g, \gamma) \mapsto D_x q\) is continuously differentiable from \(\mathcal{B}\) into \(B^{1,\lambda}_c(\mathbb{R})\).

**Proof.** This is a straightforward consequence of Theorem 4.1. One transforms (5.2) into the corresponding expression with \(\hat{\psi}\) and \(\hat{\Phi}\) replacing \(\psi\) and \(\Phi\), respectively, and uses the differentiability of \(S\). The only new ingredient is the obvious fact that the mapping \(f(x) \mapsto \int_{-\infty}^{x} f(s) ds\) is linear and continuous, and therefore continuously differentiable, from \(B^{m,\lambda}_c(\mathbb{R})\) into \(C^{m+1,\lambda}(\mathbb{R})\), for every \(m \geq 0\). \(\square\)
Remark 5.1. Concerning the behavior of \( q \) at infinity, it converges exponentially fast to zero at \(-\infty\) and exponentially fast to a constant at \(+\infty\). This observation stems from the following simple lemma.

Denote by \( B_c^{m,\lambda}(I) \) the set of restrictions of functions in \( B_c^{m,\lambda}(\mathbb{R}) \) to the interval \( I \), equipped with the obvious norm. Of course, \( B_c^{m,\lambda}(I) = C^{m,\lambda}(I) \) unless \( I \) is unbounded.

**Lemma 5.2.** The correspondences

\[
f(x) \mapsto \int_{-\infty}^{x} f(s)\,ds \quad \text{and} \quad f(x) \mapsto \int_{x}^{\infty} f(s)\,ds
\]

are linear and continuous from \( B_c^{m,\lambda}((-\infty,0]) \) into \( B_c^{m+1,\lambda}((-\infty,0]) \) and from \( B_c^{m,\lambda}([0,\infty)) \) into \( B_c^{m+1,\lambda}([0,\infty)) \), respectively.

**Proof.** The proof is similar in both cases. For the second case, say, define \( F(x) = \int_{x}^{\infty} f(s)\,ds \). Then one has immediately that

\[
\sup_{x \in [0,\infty)} e^{cx} |F(x)| \leq \sup_{x \in [0,\infty)} e^{cx} \int_{x}^{\infty} |f(s)|\,ds
\]

\[
\leq \sup_{x \in [0,\infty)} e^{cx} \int_{x}^{\infty} e^{-cs} \|f\|_{m,c,\lambda}\,ds
\]

\[
= \frac{1}{c} \|f\|_{m,c,\lambda},
\]

and the conclusion now follows. \( \square \)

**6. Proof of Theorem 3.1.** The following elementary fact will be needed to conclude the proof of Theorem 3.1.

**Lemma 6.1.** The solution map associated to the non-homogeneous ordinary differential equation

\[
(6.1) \quad \mathcal{L} T = D_x^3 T - \tau C_1 y_0 D_x^2 T + \tau C_2 D_x T + 3\tau C_1 \frac{1}{y_0} T = f
\]

is linear and continuous from \( B_c^{1,\lambda}(\mathbb{R}) \) into \( B_c^{4,\lambda}(\mathbb{R}) \) provided that the angle of inclination \( \alpha > 0 \) of the plane \( P \) is small enough and provided that, once \( \alpha \) is fixed, the decay rate \( c > 0 \) is small enough.

**Remark 6.1.** The proof of this result is postponed until Section 9, where a slightly more elaborate result about equation (6.1) is needed. The issue of exactly how small \( \alpha \)
and $c$ need to be is also dealt with there. In the notation that arises in Lemma 9.1, $\alpha$ and $c$ should be such that $0 < \sin(\alpha) < \epsilon_1$ and $0 < c < r_2(\sin(\alpha))$.

Remark 6.2. It is easily seen that the solution operator $R$ in Lemma 6.1 is continuous from $B^{1,\lambda}_c(\mathbb{R})$ to $B^{4,\lambda}_c(\mathbb{R})$ whenever the polynomial $z^3 - \tau C_1 y_0 z^2 + \tau C_2 z + 3 \tau C_1 / y_0$ has three distinct roots with non-zero real parts. For this latter condition to be valid, it suffices, but is not necessary that $\alpha$ is small. However, other restrictions on $\alpha$ appear later, and so we have eschewed stating a more general result, about the continuity of $R$ than Lemma 6.1.

Lemma 6.1 is the last major component to be used in the proof of Theorem 3.1, which is the next item on the agenda.

Proof (of Theorem 3.1). The operator $T = T(g, \gamma)$ is defined to be the solution of equation (3.4) which is written with new notation as

$$
\mathcal{L}T = D_x [(1 + (\gamma')^2)^{3/2} (-q + \chi)] - \\
- \tau C_1 y_0 D_x^2 \gamma + \tau C_2 D_x \gamma + 3 \tau \frac{C_1}{y_0} \gamma
$$

(6.2)

where $\mathcal{L}$ is defined in (6.1), $q$ is defined in (5.2) and $\chi(x) := (\nabla u \cdot n \cdot n)(x, y_0 + \gamma(x))$. First, it is readily adduced from Theorem 4.1 that the mapping $(g, \gamma) \mapsto \chi$ is continuously differentiable from the ball $\mathcal{B}$ defined in (4.10) having radius $r_0$ and centered at the origin in $B^{4,\lambda}_c(\mathbb{R}) \times B^{2,\lambda}_c(\mathbb{R})$ into $B^{2,\lambda}_c(\mathbb{R})$. In consequence of Remark 4.3 and Remark 3.1, the correspondence $(g, \gamma) \mapsto D_x [(1 + (\gamma')^2)^{3/2} \chi]$ is therefore continuously differentiable when considered as a mapping of $\mathcal{B}_0$ into $B^{3,\lambda}_c(\mathbb{R})$, where $\mathcal{B}_0$ is the ball of radius $\rho_0$ centered at the origin in $B^{4,\lambda}_c(\mathbb{R}) \times B^{4,\lambda}_c(\mathbb{R})$ and $\rho_0 > 0$ is such that, simultaneously,

$$
\rho_0 \leq r_0
$$

(6.3)

and

$$
\text{the mappings } z \mapsto (1 + z^2)^{1/2} \text{ and } z \mapsto (1 + z^2)^{3/2} \text{ are analytic in } \{z : |z| \leq \rho_0\}.
$$

(6.4)

Conditions (6.3) and (6.4) may be achieved simply by choosing $\rho_0 < \min\{r_0, 1\}$.

As for the correspondence associated with the pressure term $-D_x [(1 + (\gamma')^2)^{3/2} q]$, a similar argument to that given for the velocity term which uses Theorem 5.1 and Remarks 4.3 and 3.1 shows that this comprises a continuously differentiable mapping of $\mathcal{B}_0$ into $B^{1,\lambda}_c(\mathbb{R})$. Composing these two results with the fact that

$$
\gamma \mapsto -\tau C_1 D_x^2 \gamma + \tau C_2 D_x \gamma + 3 \tau \frac{C_1}{y_0} \gamma
$$

is obviously a continuously differentiable mapping of $B^{4,\lambda}_c(\mathbb{R})$ into $B^{2,\lambda}_c(\mathbb{R})$, and applying Lemma 6.1 leads to the desired conclusion. □
7. Solution of the Free-Surface Problem. The main result is presented and established here, namely the existence and uniqueness of the solution to Equations (2.1)–(2.3) when the angle of inclination \( \alpha \) is small enough. First, it is shown that fixed points of \( T \) comprise solutions of these equations.

**Proposition 7.1.** Let \( T \) be the mapping defined in (3.4) and suppose that \( T(g, \gamma) = \gamma \) for some pair \( (g, \gamma) \in B^4_c(\mathbb{R}) \times B^1_c(\mathbb{R}) \) that satisfies (4.2). Then for the bottom configuration \( g \) and the free-surface \( \gamma \) there exists a vector-valued function \( u \) and a scalar function \( p \) such that \( (u, p) \) defines a classical solution of (2.1)–(2.3) in \( \Omega_\gamma \).

**Proof.** Clearly all that needs to be shown is that the normal-stress condition in Equation (2.2) holds. From the definition of \( T \), it follows from the relation \( \gamma = T(g, \gamma) \) that

\[
\gamma'' = \tau \left[ (1 + (\gamma')^2)^{3/2} (-q + \chi) \right] + \text{constant}
\]

for some unknown constant. However, the behavior at \(-\infty\) of all the functions appearing in the last formula necessitates that this constant be zero, and therefore (2.2) holds. \( \square \)

The way is paved to state the principal result that emerges from our study.

**Theorem 7.2.** There exists an \( \epsilon_0 > 0 \) such that whenever \( 0 < \sin(\alpha) < \epsilon_0 \), then there exists a positive real number \( c = c(\sin(\alpha)) \), an open neighborhood \( \mathcal{N}_\alpha \) of the origin in \( B^4_c(\mathbb{R}) \) and a continuously differentiable mapping \( g \mapsto \gamma(g) \) from \( \mathcal{N}_\alpha \) into \( B^1_c(\mathbb{R}) \) such that \( T(g, \gamma(g)) = \gamma(g) \) for all \( g \in \mathcal{N}_\alpha \).

The proof of Theorem 7.2 presented here rests upon the following technical result.

**Proposition 7.3.** Let \( T_\gamma(0, 0) \) be the Fréchet derivative of \( T \) with respect to \( \gamma \) evaluated at \( (g, \gamma) = (0, 0) \). Then the mapping \( I - T_\gamma(0, 0) \) is a continuous linear isomorphism from \( B^4_c(\mathbb{R}) \) into itself provided that \( \alpha \) is near enough to zero and \( c = c(\sin(\alpha)) \) is small enough.

**Remark 7.1.** The proof of this result is given in Section 9, where the smallness requirements on \( \alpha \) and \( c \) are made precise.

**Proof (of Theorem 7.2).** Let \( T_1(g, \gamma) = \gamma - T(g, \gamma) \). Then \( T_1 \) is continuously differentiable in \( \mathcal{B}_0 \) by Theorem 3.1. Moreover, as noted earlier, we have \( T_1(0, 0) = 0 \). The conclusions of Theorem 7.2 are exactly those of the implicit-function theorem applied to \( T_1 \) at the point \( (0, 0) \), a result that is known to apply on account of Lemma 7.3. \( \square \)

8. Determination of \( T_\gamma(0, 0) \). This somewhat technical section is concerned with evaluating the vitally important linear operator \( T_\gamma(0, 0) \) in the function-space setting being used throughout. The main tools are Lemma 4.3 and Remarks 4.1 and 4.3.

Before we begin the computations, it is worth making a few preparatory observations. Consider an expression of the form \( P(\gamma, \cdots, \gamma^{(n)}) \partial_x^i \partial_y^j \) where \( P \) is some analytic function.
Its derivative with respect to $\gamma$ at $(g, \gamma) = (0, 0)$ vanishes whenever $P$ contains only terms of second order or higher in $\gamma$. For instance, an expression like $\gamma\gamma'\partial_y$ has derivative with respect to $\gamma$ in the direction $h$ given by $(\gamma h' + h\gamma')\partial_y$, which equals zero when $\gamma \equiv 0$. This elementary fact simplifies the computations that follow. In fact, it will be convenient to introduce the symbol "" which stands for the equivalence relation that two such expressions considered above are equal modulo terms whose partial derivative with respect to $\gamma$ vanishes at the origin.

With the last proviso in force, we begin the calculations. First consider the mapping introduced in Section 4, and the associated mappings $A$ and $A_0^\gamma$ (see (4.8) et seq.). For $g \equiv 0$, write

$$A_0^\gamma \hat{\psi} = -A_0^\gamma \hat{\Phi} + (0, 0, \frac{1}{3}C_1 y_0^3, 0, 0).$$

Differentiating with respect to $\gamma$ in the direction $h$ and evaluating at $\gamma \equiv 0$ yields

$$(8.1) \quad (D_\gamma A_0^\gamma(0, 0)h)\hat{\psi}_0 + AD_\gamma \hat{\psi}(0, 0)h = -(D_\gamma A_0^\gamma(0, 0)h)\hat{\Phi},$$

where $\hat{\psi}_0$ is the solution of (4.2) with $\gamma = g \equiv 0$; thus by our choice of $\hat{\Phi}$, it follows that $\hat{\psi}_0 \equiv 0$. If one defines $w(h) := D_\gamma \hat{\psi}(0, 0)h$, then $w$ is the solution of the equation

$$(8.2) \quad Aw(h) = -(D_\gamma A_0^\gamma(0, 0)h)\hat{\Phi}.$$

Using the formulae in the Appendix leads directly to the relation

$$(8.3) \quad A_0^\gamma \hat{\Phi} \sim \left( \frac{\partial^4 \hat{y}}{\partial x^4} \frac{\partial \hat{\Phi}}{\partial \hat{y}} + 2 \left[ \frac{\partial^2 \hat{y}}{\partial x^2} \left( \frac{\partial \hat{y}}{\partial y} \right) \right]^2 \frac{\partial^3 \hat{\Phi}}{\partial \hat{y}^3} + 2 \frac{\partial^3 \hat{y}}{\partial x^2 \partial y} \frac{\partial \hat{y}}{\partial y} \frac{\partial^2 \hat{\Phi}}{\partial \hat{y}^2} \right),$$

$$0, \frac{1}{3}C_1 y_0^3, 0, \frac{1}{2}(1 - \gamma'^2) \left[ \left( \frac{\partial \hat{y}}{\partial y} \right)^2 \frac{\partial^2 \hat{\Phi}}{\partial \hat{y}^2} - \frac{\partial^2 \hat{y}}{\partial x^2 \partial y} \frac{\partial \hat{\Phi}}{\partial y} \right] - 2\gamma' \left[ \frac{\partial^2 \hat{y}}{\partial x \partial y} \frac{\partial \hat{\Phi}}{\partial y} + \frac{\partial \hat{y}}{\partial x} \frac{\partial \hat{y}}{\partial y} \frac{\partial^2 \hat{\Phi}}{\partial \hat{y}^2} \right].$$

In deriving Formula (8.3), we used the fact that $\hat{\Phi}$ depends only on $\hat{y}$. Now differentiate (8.3) with respect to $\gamma$ and use the explicit form of the term $\frac{\partial^p \hat{y}}{\partial x^p \partial y^{p - k}}$ to obtain

$$(8.4) \quad D_\gamma A_0^\gamma \hat{\Phi}(0, 0)h = \left( -\hat{y} \frac{h''}{y_0} \frac{\partial \hat{\Phi}}{\partial \hat{y}} - 2 \left[ -\hat{y} \frac{h''}{y_0} \frac{\partial^3 \hat{\Phi}}{\partial \hat{y}^3} + 2 \frac{h''}{y_0} \frac{\partial^2 \hat{\Phi}}{\partial \hat{y}^2} \right] \right), 0, 0, 0,$$

$$\frac{1}{2} \left[ -2 \frac{h}{y_0} \frac{\partial \hat{\Phi}}{\partial \hat{y}} + \frac{\hat{y}}{y_0} \frac{h''}{\partial \hat{y}} \right](\hat{y}, y_0).$$

Substituting the explicit form $C_1 \left( \frac{1}{2} y_0 \hat{y}^2 - \frac{1}{6} \hat{y}^3 \right)$ for $\hat{\Phi}$ leads to

$$(8.5) \quad D_\gamma A_0^\gamma \hat{\Phi}(0, 0)h = \left( -C_1 \frac{\hat{y}}{y_0} \left( y_0 \hat{y} - \frac{1}{2} \hat{y}^2 \right) h''' + 2 \left( C_1 \frac{\hat{y}}{y_0} - \frac{2C_1(y_0 - \hat{y})}{y_0} \right) h'' \right),$$

$$0, 0, 0, \frac{1}{4}C_1 y_0^2 h''.$$
Lemma 8.1. For \( h \in B_{c}^{4,\lambda}(\mathbb{R}) \), let \( w = w(h) \) connote the derivative \( D_{\gamma}S(0,0)h \). Then \( w(h) \) is the solution of the boundary value problem

\[
\begin{align*}
\Delta^2 w &= C_1 \frac{\hat{y}}{y_0} \left( y_0 \hat{y} - \frac{1}{2} \hat{y}^2 \right) h'''(\hat{x}) - \frac{2C_1}{y_0} \left( 3\hat{y} - 2y_0 \right) h''(\hat{x}), \\
\left. w(\hat{x},0) = w(\hat{x},y_0) = 0, \quad \hat{x} \in \mathbb{R}, \right. \\
\left. \frac{\partial w}{\partial \hat{y}}(\hat{x},0) = 0, \quad \hat{x} \in \mathbb{R}, \right. \\
\left. \frac{\partial^2 w}{\partial \hat{y}^2}(\hat{x},y_0) = -\frac{1}{2} C_1 y_0^2 h''(\hat{x}), \quad \hat{x} \in \mathbb{R}. \right.
\end{align*}
\tag{8.6}
\]

The partial derivative of the mapping \( (g, \gamma) \mapsto D_{x}((1 + \gamma^2)^{3/2}(-g \chi)) \), where \( q \) and \( \chi \) are as in (5.2) and (6.2) is now determined. Clearly we have

\[
D_{x}[(1 + \gamma^2)^{3/2}(-g \chi)] \sim D_{x}(-q \chi).
\]

Thus there are two terms to compute. In the original variables \((x,y)\), formula (5.1) gives

\[
D_{x}q = q' = C_1 + C_2 \gamma' + \Delta \frac{\partial}{\partial y} (\psi + \Phi) - \gamma' \Delta \frac{\partial}{\partial x} (\psi + \Phi),
\]

wherein both \( \Phi \) and \( \psi \) are evaluated at \( y = y_0 + \gamma(x) \); thus it follows that

\[
q' \sim C_2 \gamma' + \Delta \frac{\partial}{\partial y} (\psi + \Phi).
\]

Using the formulae listed in the Appendix again and taking derivatives with respect to \( \gamma \) then leads to the relation

\[
D_{\gamma}q'(0,0)h = -C_1 \frac{y_0}{2} h'' + 3 \frac{C_1}{y_0} h + C_2 h' + \frac{\partial^3 w}{\partial \hat{x}^2 \partial \hat{y}}(\cdot, y_0) + \frac{\partial^3 w}{\partial \hat{y}^3}(\cdot, y_0).
\tag{8.8}
\]

A similar argument works for the term involving \( \chi \), and the outcome is that

\[
D_{\gamma} \chi'(0,0)h = -\frac{\partial^3 w}{\partial \hat{x}^2 \partial \hat{y}}(\cdot, y_0) + C_1 \frac{y_0}{2} h''.
\tag{8.9}
\]

These results are summed up in the following proposition.

Proposition 8.3. Let \( h \) lie in \( B_{c}^{4,\lambda}(\mathbb{R}) \). The mapping \( T_{\gamma}(0,0) \) is the continuous linear operator that associates to \( h \) the solution \( v = v(h) \) of the equation

\[
L_{\tau} v = v''' - \tau C_1 y_0 v'' + \tau C_2 v' + 3\tau \frac{C_1}{y_0} v = \tau \left( -2 \frac{\partial^3 w}{\partial x^2 \partial y}(\cdot, y_0) - \frac{\partial^3 w}{\partial y^3}(\cdot, y_0) \right)
\tag{8.10}
\]

where \( w \) is the solution of (8.6) associated with \( h \). (Here, and henceforth, the circumflexes have been dropped.)

Proof. When the derivative with respect to \( \gamma \) is extracted from the right-hand side of (6.2), the only remaining terms are precisely those on the right-hand side of (8.10). □
9. Invertibility of \( I - T_\gamma(0,0) \). In this section a proof of Lemma 7.3 is provided. This lemma was crucial for justifying the application of the implicit-function theorem. Let \( f \) be given in \( B^{1,\lambda}_c(\mathbb{R}) \) and consider solving for \( h \) the equation

\[
(I - T_\gamma(0,0))h = f,
\]

where \( I \) denotes the identity mapping. If we consider the difference \( h - f \), then this quantity is a solution of (8.10), which is to say that

\[
\mathcal{L}(h - f) = -\tau \left( 2 \frac{\partial^3 w}{\partial x^2 \partial y} + \frac{\partial^3 w}{\partial y^3} \right) \left( \cdot, y_0 \right)
\]

where \( w \) is the solution of (8.6) and \( \mathcal{L} \) is the linear, ordinary differential operator defined in (6.1), or what is the same,

\[
(9.1) \quad \mathcal{L}h = -\tau \left( 2 \frac{\partial^3 w}{\partial x^2 \partial y} + \frac{\partial^3 w}{\partial y^3} \right) \left( \cdot, y_0 \right) + \mathcal{L}f.
\]

The proof of existence of a unique solution \( h \) of (9.1) rests upon the following technical lemmas.

**Lemma 9.1.** Let \( f \in B^{1,\lambda}_c(\mathbb{R}) \) and consider the differential equation

\[
(9.2) \quad v''' - a_1 \epsilon v'' - a_2 \sqrt{1-\epsilon^2} v' + a_3 \epsilon v = f
\]

for \( x \in \mathbb{R} \), where the \( a_i \) are positive constants, \( 1 \leq i \leq 3 \). There exists an \( \epsilon_1 > 0 \) and a constant \( K_1 \) depending only on \( a_1, a_2, a_3 \) such that whenever \( 0 < \epsilon < \epsilon_1 \), then

(i) the polynomial \( P_\epsilon(z) = z^3 - a_1 \epsilon z^2 - a_2 \sqrt{1-\epsilon^2} z + a_3 \epsilon \) has three distinct real roots \( r_1(\epsilon), r_2(\epsilon), r_3(\epsilon) \) with \( r_1(\epsilon) < -r_2(\epsilon) < 0 < r_2(\epsilon) < r_3(\epsilon) \),

(ii) for every \( c \) with \( 0 < c < r_2(\epsilon) \), and every \( f \) in \( B^{1,\lambda}_c(\mathbb{R}) \), (9.2) has a unique solution \( v \) in \( B^{4,\lambda}_c(\mathbb{R}) \) and, moreover, \( v \) satisfies the estimate

\[
\|v\|_{c,4,\lambda} \leq K_1 \left( 1 + \frac{1}{r_2(\epsilon) - c} \right) \|f\|_{c,1,\lambda}, \quad \text{and}
\]

(iii) if in addition \( f = \tilde{f}' \) for some \( \tilde{f} \) in \( B^{2,\lambda}_c(\mathbb{R}) \), then \( v \) satisfies the further estimate:

\[
\|v\|_{c,4,\lambda} \leq K_1 \left( 1 + \frac{r_2(\epsilon)}{r_2(\epsilon) - c} \right) \|\tilde{f}'\|_{c,2,\lambda}.
\]
Proof. As \( \epsilon \downarrow 0 \), \( r_1(\epsilon) \) and \( r_3(\epsilon) \) tend to \(-\sqrt{a_2}\) and \(\sqrt{a_2}\), respectively, while \( r_2(\epsilon) \) tends to zero. It follows more or less immediately that for small \( \epsilon, P_\epsilon \) has three real roots as advertised in part (i). Furthermore, one easily verifies that \( r_2(\epsilon)/\epsilon \) and \( \epsilon/r_2(\epsilon) \) are bounded in any bounded neighborhood of 0.

To establish (ii), proceed as follows. The general form of the solution of (9.1) is

\[
v(x) = A_1 e^{r_1 x} + A_2 e^{r_2 x} + A_3 e^{r_3 x} + \lambda_1 e^{r_1 x} \int_0^x e^{-r_1 s} f(s) ds + \lambda_2 e^{r_2 x} \int_0^x e^{-r_2 s} f(s) ds + \lambda_3 e^{r_3 x} \int_0^x e^{-r_3 s} f(s) ds
\]

where \( r_i = r_i(\epsilon), 1 \leq i \leq 3 \), and \( (\lambda_1, \lambda_1, \lambda_3) \) is the solution of the system of equations

\[
\begin{align*}
\lambda_1 + \lambda_2 + \lambda_3 &= 0, \\
r_1 \lambda_1 + r_2 \lambda_2 + r_3 \lambda_3 &= 0, \\
r_1^2 \lambda_1 + r_2^2 \lambda_2 + r_3^2 \lambda_3 &= 1,
\end{align*}
\]

so that

\[
\begin{pmatrix} \lambda_1 \\ \lambda_2 \\ \lambda_3 \end{pmatrix} = \frac{1}{(r_1 - r_2)(r_2 - r_3)(r_3 - r_1)} \begin{pmatrix} r_2 r_3^2 - r_2^2 r_3 & r_2^2 - r_3^2 & r_3 - r_2 \\ r_1^2 r_3 - r_1 r_2^2 & r_1^2 - r_2^2 & r_2 - r_1 \\ r_1 r_2^2 - r_1^2 r_2 & r_1^2 - r_2^2 & r_2 - r_1 \end{pmatrix} \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}.
\]

If we insist that \( v \) vanish at \( \infty \), then since \( r_1 \) is negative and \( r_2 \) and \( r_3 \) positive, it is clear that the constants \( A_1, A_2, A_3 \) must be chosen so that

\[
v(x) = \lambda_1 e^{r_1 x} \int_{-\infty}^x e^{-r_1 s} f(s) ds + \lambda_2 e^{r_2 x} \int_{+\infty}^x e^{-r_2 s} f(s) ds + \lambda_3 e^{r_3 x} \int_{+\infty}^x e^{-r_3 s} f(s) ds.
\]

It is also clear that \( v \) lies in \( C^{4,\lambda}(R) \) whenever \( f \) lies in \( C^{1,\lambda}(R) \), so it is the behaviour of \( v \) at \( \infty \) that becomes the focus of attention. Fix a value of \( c \) in the range \( 0 < c < r_2 \), and assume that \( f \in B^{1,\lambda}(R) \). Setting \( \|f\|_{c,1,\lambda} = M \), we may estimate the first integral as follows:

(9.4) \[
\left| \lambda_1 e^{r_1 x} \int_{-\infty}^x e^{-r_1 s} f(s) ds \right| \leq \left| \lambda_1 e^{r_1 x} \int_{-\infty}^x M e^{-r_1 s} e^{-c|s|} ds \right|.
\]

For \( x \leq 0 \), the inequality in (9.4) yields the estimate

\[
\left| \lambda_1 e^{r_1 x} \int_{-\infty}^x e^{-r_1 s} f(s) ds \right| \leq \left| \lambda_1 \right| e^{r_1 x} \int_{-\infty}^x M e^{(c-r_1)s} ds
\]

\[
= \frac{\left| \lambda_1 \right| M e^{-c|x|}}{c - r_1}
\]

18
because \( c - r_1 > 0 \). For \( x \geq 0 \), we proceed a little differently;

\[
\left| \lambda_1 e^{r_1 x} \int_{-\infty}^{x} e^{-r_1 s} f(s) ds \right| \leq |\lambda_1| e^{r_1 x} \int_{-\infty}^{0} e^{-r_1 s} M e^{cs} ds + |\lambda_1| e^{r_1 x} \int_{0}^{x} e^{-r_1 s} M e^{-cs} ds
\]

\[
\leq |\lambda_1| M e^{r_1 x} \left( \frac{1}{c - r_1} + \frac{1 - e^{-(r_1 + c)x}}{r_1 + c} \right)
\]

\[
\leq \frac{|\lambda_1| M}{c - r_1} e^{r_1 x} + \frac{|\lambda_1| M}{c + r_1} \left( e^{r_1 x} - e^{-cx} \right).
\]

By inspection, it is seen that \( e^{c|x|}|v(x)| \) is bounded if \( 0 < c < |r_1| \). The other integrals are dealt with similarly, and thereby the estimate

\[
\sup_{x \in \mathbb{R}} |v(x)| e^{c|x|} \leq \|f\|_{c,1,\lambda} \left\{ \sum_{i=1}^{3} 2|\lambda_i| \left( \frac{1}{|c - r_i|} + \frac{1}{|c + r_i|} \right) \right\}
\]

(9.5) obtains. As for the derivatives of \( v \), the inequalities

\[
\sup_{x \in \mathbb{R}} |v^{(k)}(x)| e^{c|x|} \leq \|f\|_{c,1,\lambda} \left\{ \sum_{i=1}^{3} 2|\lambda_i| |r_i|^k \left( \frac{1}{|c - r_i|} + \frac{1}{|c + r_i|} \right) \right\}
\]

(9.6) follow by the same means for \( 0 \leq k \leq 3 \). As for the norm of \( v''' \), we simply differentiate once the equation satisfied by \( v \) and use the estimates above to obtain that

\[
\sup_{x \in \mathbb{R}} e^{c|x|} |v'''(x)| \leq \left\{ \|f\|_{c,1,\lambda} + a_3 \varepsilon \sup_{x \in \mathbb{R}} e^{c|x|} |v'(x)| + a_2 \varepsilon \right\}
\]

\[
+ a_1 \varepsilon \sup_{x \in \mathbb{R}} e^{c|x|} |v'''(x)|
\]

and that

\[
\sup_{(x,x') \in \mathbb{R}^2, x \neq x'} \frac{|v'''(x) - v'''(x')|}{|x - x'|^{\lambda}} \leq 2 \sup_{x \in \mathbb{R}} |v'''(x)| + \sup_{x \neq x', |x - x'| < 1} \frac{|v'''(x) - v'''(x')|}{|x - x'|^{\lambda}}
\]

\[
\leq 2 \sup_{x \in \mathbb{R}} |v'''(x)| + \sup_{x \neq x'} \frac{|f'(x) - f'(x')|}{|x - x'|^{\lambda}}
\]

\[
+ a_3 \varepsilon \sup_{x \in \mathbb{R}} |v''(x)| + a_2 \varepsilon \sup_{x \in \mathbb{R}} |v'''(x)| + a_1 \varepsilon \sup_{x \in \mathbb{R}} |v'''(x)|
\]

where we used the equation a second time in the last step. Whenever \( 0 < \varepsilon < \varepsilon_1 \) and \( 0 < c < r_2(\varepsilon) \), the quantities \( \frac{r_i^{k}}{r_i \pm c} \) for \( i = 1, 3 \), are uniformly bounded. Appropriately
grouping the terms appearing above, we obtain (ii) with some constant \( K_1 \) that may be chosen independently of \( \varepsilon \) in the range \( 0 < \varepsilon < \varepsilon_1 \).

For the proof of (iii), consider for instance the term \( e^{r_1 x} \int_{-\infty}^{x} e^{-r_1 s} \tilde{f}'(s)ds \), and perform a (legitimate) integration by parts to obtain that

\[
e^{r_1 x} \int_{-\infty}^{x} e^{-r_1 s} \tilde{f}'(s)ds = \tilde{f}(x) + r_1 e^{r_1 x} \int_{-\infty}^{x} e^{-r_1 s} \tilde{f}(s)ds.
\]

Obviously, the estimates for \( v \) are the same as in the previous case, except that there are three extra terms featuring \( \tilde{f} \) as above, and these have a multiplicative factor \( r_i \) associated with them. The result thus follows easily. □

**Corollary 9.2.** Under the assumptions of Lemma 9.1, we may conclude that

\[
\|v\|_{\frac{1}{2} r_2(\varepsilon), 4, \lambda} \leq K_2 \|\tilde{f}\|_{\frac{1}{2} r_2(\varepsilon), 2, \lambda}
\]

whenever \( v \) is the solution of (9.2) in which the right-hand side is \( \tilde{f}' \), and \( K_2 \) depends only on \( a_1, a_2 \) and \( a_3 \).

**Proof.** This follows immediately from Lemma 9.1, part (iii), with \( K_2 = 3K_1 \). □

**Lemma 9.3.** Let \( W \) be the solution of the boundary value problem:

\[
\begin{align*}
\Delta^2 W(x, y) &= \left(y^2 - \frac{1}{2} \frac{y^3}{y_0}\right) h'''(x) - \frac{2}{y_0}(3y - 2y_0)h''(x) & \text{for } (x, y) \in \Sigma, \\
W(x, 0) &= W(x, y_0) = \frac{\partial W}{\partial y}(x, 0) = 0 & \text{for } x \in \mathbb{R}, \\
\frac{\partial^2 W}{\partial y^2}(x, y_0) &= -\frac{1}{2} y_0^2 h''(x) & \text{for } x \in \mathbb{R},
\end{align*}
\]

(9.7)

where \( h \) is a given function in \( B^{1,\lambda}_c(\mathbb{R}) \). Define \( \rho \) to be

\[
\rho(x) = C_0 \tau \left\{ 2 \frac{\partial^3 W}{\partial x^2 \partial y}(x, y_0) + \frac{\partial^3 W}{\partial y^3}(x, y_0) \right\}.
\]

Then there exists a \( c_1 > 0 \) such that whenever \( 0 \leq c \leq c_1 \), then:

(i) \( \rho(x) \in B^{1,\lambda}_c(\mathbb{R}) \) and \( \rho(x) = \tilde{\rho}'(x) \) for some function \( \tilde{\rho} \) in \( B^{2,\lambda}_c(\mathbb{R}) \);

(ii) the mapping \( h \rightarrow \tilde{\rho} \) is linear and continuous from \( B^{1,\lambda}_c(\mathbb{R}) \) into \( B^{2,\lambda}_c(\mathbb{R}) \);

(iii) there exists a constant \( K_3 \) depending only on \( y_0 \) with the property that \( \|\rho\|_{c, 2, \lambda} \leq \tau C_0 K_3 \|h\|_{c, 4, \lambda} \).
Proof. Consider the solution $Z$ of
\[
\begin{align*}
\Delta^2 Z(x, y) &= \left(y^2 - \frac{1}{2} \frac{y^3}{y_0}\right) h'''(x) - \frac{2}{y_0} (3y - 2y_0) h'(x) \quad \text{for } (x, y) \in \Sigma, \\
Z(x, 0) &= Z(x, y) = \frac{\partial Z}{\partial y}(x, 0) = 0 \quad \text{for } x \in \mathbb{R}, \\
\frac{\partial^2 Z}{\partial y^2}(x, y_0) &= -\frac{1}{2} y_0^2 h'(x) \quad \text{for } x \in \mathbb{R}.
\end{align*}
\]

By Corollary 10.1, we deduce that $W \in B_{\tilde{c}}^{5, \lambda}(\tilde{\Sigma})$ for $0 < c < \tilde{c}$, where $\tilde{c}$ is as in Proposition 4.2. Plainly we have that
\[
W(x, y) = \frac{\partial Z}{\partial x}(x, y) \quad \text{for } (x, y) \in \tilde{\Sigma}.
\]

As a matter of fact, $W$ and $\frac{\partial Z}{\partial x}$ are solutions of the same boundary-value problem, and this solution is unique by Proposition 4.2. This conclusion implies that $\tilde{\rho}(x) := C_0 \tau \left\{ \frac{2 \partial^2 Z}{\partial x^2 y}(x, y_0) + \frac{\partial^2 Z}{\partial y^2}(x, y_0) \right\}$ is such that
\[
\rho(x) = \tilde{\rho}'(x),
\]
and (i) is proved. Property (ii) is obvious, and (iii) is proved as follows. Using Proposition 4.2 (and see also Corollary 10.1), we fix a value $c_1$ with $0 < c_1 < \tilde{c}$ and obtain a constant $K_3$ depending only on $y_0$ such that
\[
\|Z\|_{c, 5, \lambda} \leq K_3 \|h\|_{c, 4, \lambda}
\]
whenever $0 \leq c \leq c_1$. Thus (iii) is established.

Here is the main result of this section.

**Lemma 9.4.** Consider the equation
\[
h''' - a_1 \epsilon h'' - a_2 \sqrt{1 - \epsilon^2} h' + a_3 \epsilon h + \epsilon \rho = (f''' - a_1 \epsilon f'' - a_2 \sqrt{1 - \epsilon^2} f' + a_3 \epsilon f)
\]
where $f \in B_{c}^{4, \lambda}(\mathbb{R})$, and $\rho$ is defined in Lemma 9.3. There exists an $\epsilon_0 > 0$ such that (9.8) has a unique solution $h$ in $B_{c(\epsilon)}^{4, \lambda}(\mathbb{R})$ whenever $0 < \epsilon < \epsilon_0$, where $c(\epsilon) = \frac{1}{2} r_2(\epsilon)$ and $r_2(\epsilon)$ is as introduced in Lemma 9.1, and $f$ is a given function in $B_{c(\epsilon)}^{4, \lambda}(\mathbb{R})$.

**Proof.** Denoting by $P_\epsilon(D)$ the operator $D_x^3 - a_1 \epsilon D_x^2 - a_2 \sqrt{1 - \epsilon^2} D_x + a_3 \epsilon$, we may write (9.8) in the form
\[
(9.8)' \quad h + \epsilon (P_\epsilon(D)^{-1} \rho) = f.
\]
From Lemma 9.3 and Corollary 9.2, one deduces that if $0 < \epsilon < \epsilon_1$ and $0 < \frac{1}{2} r_2(\epsilon) \leq c_1$, then
\[
\|P_\epsilon(D)^{-1} \rho\|_{c(\epsilon), 4, \lambda} \leq \tau C_0 K_4 \|h\|_{c(\epsilon), 4, \lambda},
\]
where $K_4 = K_3 K_2$ depends only on $y_0$. Therefore, the norm of the linear mapping $h \mapsto \epsilon P_\epsilon(D)^{-1} \rho$ is bounded from above by $\epsilon C_0 \tau K_4$.

From Lemma 9.1 part (i), we know it is possible to choose $\epsilon_0$ meeting all of the following requirements:

\[
0 < \epsilon < \epsilon_1, \quad 0 < \sup_{0 < \epsilon < \epsilon_0} \left\{ \frac{1}{2} r_2(\epsilon) \right\} < c_0 \quad \text{and} \quad \epsilon_0 C_0 \tau K_4 < 1.
\]

Then for any positive $\epsilon < \epsilon_0$, the operator $I + \epsilon P_\epsilon(D)^{-1} \rho$, when considered as a self-mapping of $B_{c(\epsilon)}^4(\mathbb{R})$ is boundedly invertible. Thus the lemma is established. \(\square\)

**Proof (of Proposition 7.3).** To conclude the proof of Proposition 7.3, apply Lemma 9.4 with $a_1 = \tau C_0 y_0, a_2 = \tau C_0, a_3 = 3 \tau C_0 / y_0$ and $\epsilon = \sin(\alpha)$. \(\square\)

**10. Proof of Proposition 4.2.** The final piece of the argument is completed here, namely a proof of Proposition 4.2 concerning the solvability of a certain boundary-value problem in the spaces appropriate to our theory.

First, consider the homogeneous problem

\[
\begin{aligned}
\Delta^2 v &= f_1 & \text{in } \mathbb{R},
\frac{\partial v}{\partial y}(\cdot, 0) = 0 & \frac{\partial^2 v}{\partial y^2}(\cdot, y_0) = 0 & \text{in } \mathbb{R},
\end{aligned}
\]

and introduce the Green’s function $\mathcal{G}$ associated to (10.1). Because of the structure of the problem, $\mathcal{G}(x, y; x', y')$ can be written as $G(x - x', y, y')$ where $G$ enjoys the following properties: there is a constant $C > 0$ such that

\[
\begin{align*}
|D^4 G(x - x', y, y')| &\leq C(|x - x'| + |y - y'|)^{-2}, \\
|D^3 G(x - x', y, y')| &\leq C(|x - x'| + |y - y'|)^{-1}, \\
|D^2 G(x - x', y, y')| &\leq C \log(|x - x'| + |y - y'|), \\
|DG(x - x', y, y')| &\leq C, \\
|G(x - x', y, y')| &\leq C,
\end{align*}
\]

whenever $|x - x'| \leq 2$ and $D^k$ is any differential operator in the variables $x$ and $y$ of order $k$, and there is a positive constant $\tilde{c}$ such that

\[
|D^k G(x - x', y, y')| \leq C e^{-\tilde{c}|x - x'|}
\]

for $|x - x'| \geq 2$, and $0 \leq k \leq 4$. These results are essentially in Amick (1977 & 1978, Theorem 4.1), modulo minor modifications imposed by the boundary conditions.
Under the assumption that $f_1 \in B^3_c(\Sigma)$ for some $c$ with $0 < c < \tilde{c}$, we now prove that $v \in B^4_c(\Sigma)$. First of all, there exists a weak solution $v \in \tilde{H}^4(\Sigma) := \{ v \in H^4(\Sigma) : v(\cdot, 0) = v(\cdot, y_0) = \frac{\partial v}{\partial y}(\cdot, y_0) = \frac{\partial^2 v}{\partial y^2}(\cdot, y_0) = 0 \}$ because $\Delta^2$ is a coercive, self adjoint operator from $\tilde{H}^4(\Sigma)$ into $L^2(\Sigma)$ and $f_1$ obviously belongs to $L^2(\Sigma)$. Applying standard arguments, we obtain that $v$ is a classical solution in $C^4(\Sigma)$. Concerning the weighted norm, use the Green's function to write

\begin{equation}
(10.4) \quad v(x, y) = \int_{\Sigma} G(x - x', y, y') f_1(x', y') \, dx' \, dy'
\end{equation}

so that

\[
|v(x, y)| e^{c|x|} \leq e^{c|x|} \left( C \int_{|x - x'| \geq 2} e^{-\tilde{c}|x-x'|} f_1(x', y') \, dy' \, dx' + C \int_{|x - x'| \leq 2} f_1(x', y') dy' \, dx' \right).
\]

Let $M = \sup_{(x, y) \in \Sigma} e^{c|x|} |f_1(x, y)|$ and continue the estimate in the last display as follows:

\[
|v(x, y)| e^{c|x|} \leq e^{c|x|} CM \left( \int_{-\infty}^{x-2} y_0 e^{-\tilde{c}(x-x')} e^{-c|x'|} \, dx' + \int_{x-2}^{x+2} y_0 e^{-\tilde{c}(x'-x)} e^{-c|x'|} \, dx' + \int_{x+2}^{\infty} y_0 e^{-c|x'|} \, dx' \right).
\]

Attention is first drawn to the case wherein $x \to -\infty$. Assuming that $x + 2 \leq 0$, the
inequality (10.5) yields

\[
|v(x, y)| e^{c|x|} \leq CM y_0 e^{c|x|} \left( \int_{-\infty}^{z-2} e^{-\tilde{c}(x-x')} e^{c x'} dx' + \int_{z+2}^{0} e^{-\tilde{c}(x-x')} e^{c x'} dx' + \right.
\]

\[
\left. + \int_{0}^{+\infty} e^{-\tilde{c}(x-x')} e^{-c x'} dx' + 4e^{-c|x-2|} \right) \right)
\]

\[
\leq CM y_0 e^{c|x|} \left( e^{-\tilde{c}x} \left[ \frac{e^{(c+\tilde{c})x'} - e^{-c x'}}{c + \tilde{c}} \right]_{-\infty}^{x-2} + e^{\tilde{c}x} \left[ \frac{e^{(c-\tilde{c})x'}}{c - \tilde{c}} \right]_{+\infty}^{0} \right.
\]

\[
\left. + e^{\tilde{c}x} \left[ \frac{-e^{-(c+\tilde{c})x'}}{c + \tilde{c}} \right]_{0}^{+\infty} + 4e^{-2c e^{c x}} \right)
\]

\[
\leq CM y_0 e^{-c x} \left( \frac{e^{c x} e^{-2(c+\tilde{c})}}{c + \tilde{c}} + \frac{e^{c x} e^{2(c-\tilde{c})} - e^{\tilde{c} x}}{\tilde{c} - c} + \frac{e^{\tilde{c} x}}{c + \tilde{c}} \right) + 4e^{-2c e^{c x}}
\]

and

\[
|v(x, y)| e^{c|x|} \leq CM y_0 \left( \frac{e^{-2(c+\tilde{c})}}{c + \tilde{c}} + \frac{e^{2(c-\tilde{c})} - e^{(\tilde{c}-c)x}}{\tilde{c} - c} + \frac{e^{(\tilde{c}-c)x}}{c + \tilde{c}} + 4e^{-2c e^{c x}} \right).
\]

When \( x \to +\infty \), similar considerations lead to the conclusion that there exists a constant \( K_5 \) for which

\[
\sup_{(x, y) \in \Sigma} |v(x, y)| e^{c|x|} \leq K_5 \left( \frac{1}{c + \tilde{c}} + \frac{1}{c - \tilde{c}} + 1 \right) \|f_1\|_{0, c, \lambda},
\]

where \( K_5 \) depends only on \( y_0 \). Furthermore, it is clear that as a function of \( c, K_5 \) is bounded on any compact subinterval of \([0, \tilde{c})\). We proceed in exactly the same fashion to obtain an estimate for the weighted norm of the derivatives of \( v \) of order up to three. The technique is identical to that just outlined because differentiation under the integral sign is legitimate since the second-and third-order derivatives of \( G \) have integrable singularities at \( x = x', y = y' \). Once again, we obtain constants that are bounded when \( c \) is bounded away from \( \tilde{c} \). Finally, to estimate the weighted norm of the fourth-order derivatives of \( v \), consider the function \( w(x)v(x, y) \) where \( w \in C^\infty(\mathbb{R}), w = e^{c|x|} \) for \( |x| \geq 1 \) and \( w \geq w_0 > 0 \), and work out the boundary-value problem to which this function \( wv \) is the solution. The
conclusion follows from the classical Hölder estimates for elliptic equations since all the lower-order derivatives of uv are already known to be bounded.

For the case of non-homogeneous boundary conditions, use is made of a succession of lifting operators. We want to solve (4.6), namely

\[
\begin{cases}
\Delta^2 v = f_1 & \text{for} \; (x, y) \in \Sigma, \\
\frac{\partial v}{\partial y}(\cdot, 0) = f_3, & \frac{\partial^2 v}{\partial y^2}(\cdot, y_0) = f_5, \\
v(\cdot, 0) = f_2, & v(\cdot, y_0) = f_4, \; \text{for} \; x \in \mathbb{R}.
\end{cases}
\]

(10.6)

Begin by subtracting from \( v \) the function \( f_2(y_0 - y)/y_0 + f_4y/y_0 \) to obtain the function \( v_1 \) which is a solution of

\[
\begin{cases}
\Delta^2 v_1 = f_1 - \Delta^2 \left( \frac{y_0 - y}{y_0} f_2 + \frac{y}{y_0} f_4 \right) := k_1, & \text{in} \; \Sigma, \\
v_1(\cdot, 0) = v_1(\cdot, y_0) = 0 & \text{in} \; \mathbb{R}, \\
\frac{\partial v_1}{\partial y}(\cdot, y_0) = f_3 - \frac{\partial}{\partial y} \left( \frac{y_0 - y}{y_0} f_2 + \frac{y}{y_0} f_4 \right) := k_2 & \text{in} \; \mathbb{R}, \\
\frac{\partial^2 v_1}{\partial y^2}(\cdot, y_0) = f_5 & \text{in} \; \mathbb{R},
\end{cases}
\]

and \( v = v_1 + \left( \frac{y_0 - y}{y_0} f_2 + \frac{y}{y_0} f_4 \right) \). Next, write

\[
v_1 = v_2 + \left( 1 - \frac{y}{y_0} \right) \int_x^{x+y} k_2(s) ds,
\]

where \( v_2 \) is the solution of

\[
\begin{cases}
\Delta^2 v_2 = k_1 - \Delta^2 \left[ \left( 1 - \frac{y}{y_0} \right) \int_x^{x+y} k_2(s) ds \right] := k_3 & \text{in} \; \Sigma, \\
v_2(\cdot, 0) = v_2(\cdot, y_0) = 0, & \text{in} \; \mathbb{R}, \\
\frac{\partial v_2}{\partial y}(\cdot, 0) = 0, \frac{\partial^2 v_2}{\partial y^2}(\cdot, y_0) = f_5 + \frac{1}{y_0} \int_x^{x+y_0} k_2(s) ds := k_4 & \text{in} \; \mathbb{R}.
\end{cases}
\]

Finally, we set

\[
v_2 = v_3 + \left( -\frac{2y^3}{y_0^3} + 3\frac{y^2}{y_0^2} \right) \int_x^{x+y_0} \int_x^t k_4(s) ds dt,
\]

and \( v_3 \) is now the solution of the homogenous problem in 10.1. It just remains to check that the modifications above take place in the proper function spaces, and this is straightforward. \( \square \)

As a corollary of the above proof, we have the following result which found use in Section 9.
Corollary 10.1. The conclusions of Proposition 4.2 hold when \((f_i)_{1 \leq i \leq 5}\) lies in \(B^{1,\lambda}_{c}(\Sigma) \times B^{5,\lambda}_{c}(\mathbb{R}) \times B^{4,\lambda}_{c}(\mathbb{R}) \times B^{3,\lambda}_{c}(\mathbb{R}) \times B^{3,\lambda}_{c}(\mathbb{R})\), provided that the norm on \(v\) is that of \(B^{3,\lambda}_{c}(\Sigma)\) throughout.

Proof. First reduce the problem to a homogenous one using the method in the last proof, and then use the representation formula (10.4) for \(v\) to prove that \(\frac{\partial v}{\partial x}\) is in \(B^{3,\lambda}_{c}(\Sigma)\). In due course, use is made of the equation to establish that \(\partial^4 v / \partial y^4\) is in \(B^{1,\lambda}_{c}(\Sigma)\). The conclusion follows. \(\square\)

Appendix. Here are recorded the formulae relating to the change of variable \((x, y) \mapsto (\hat{x}, \hat{y})\) which was used to map the original boundary-value problem to an associated boundary-value problem on a fixed domain.

First we compute the partial derivatives of this mapping when the bottom is flat, that is when \(g \equiv 0\). In this case, one has

\[
\hat{x} = x, \quad \hat{y} = \frac{y_0 y}{y_0 + \gamma},
\]

so that

\[
\frac{\partial \hat{y}}{\partial y} = \frac{y_0}{y_0 + \gamma} \quad \text{and} \quad \frac{\partial^p \hat{y}}{\partial y^p} = 0 \quad \text{for} \quad p \geq 2,
\]

\[
\frac{\partial^p \hat{y}}{\partial x^p \partial y} = \frac{y_0}{y_0 + \gamma} \frac{\partial^{p-1} \hat{y}}{\partial x^{p-1}},
\]

\[
\frac{\partial \hat{y}}{\partial x} = \frac{-\hat{y}' y}{y_0 + \gamma}, \quad \frac{\partial^2 \hat{y}}{\partial x^2} = \hat{y} \left( 2 \frac{\gamma''}{(y_0 + \gamma)^2} - \frac{\gamma'''}{(y_0 + \gamma)} \right),
\]

\[
\frac{\partial^3 \hat{y}}{\partial x^3} = \hat{y} \left( \frac{-\gamma'''}{(y_0 + \gamma)} + \frac{6\gamma'\gamma''}{(y_0 + \gamma)^2} - \frac{6\gamma'^3}{(y_0 + \gamma)^3} \right),
\]

\[
\frac{\partial^4 \hat{y}}{\partial x^4} = \hat{y} \left( \frac{-\gamma''''}{(y_0 + \gamma)} + \frac{8\gamma'\gamma'''}{(y_0 + \gamma)^2} + \frac{36\gamma'^3\gamma''}{(y_0 + \gamma)^3} - \frac{24\gamma'\gamma''}{(y_0 + \gamma)^4} \right).
\]

Next, we record the transformation of the associated differential operators, retaining only those terms that yield a non-zero contribution after the derivative with respect to \(\gamma\) is extracted and the result evaluated at \(\gamma = g \equiv 0\). We continue to use the equivalence relation \(\sim\) introduced in Section 8 to denote equality modulo terms whose partial derivative with respect to \(\gamma\) vanishes at the origin.
